

**Applications of Fe<sub>3</sub>O<sub>4</sub>@AC nanoparticles for dye removal from simulated wastewater**Seema Joshi<sup>a</sup>, V. K. Garg<sup>a,b\*</sup>, Navish Kataria<sup>b</sup>, K. Kadirvelu<sup>c</sup><sup>a</sup>*Department of Environmental Science and Engineering, Guru Jambheshwar University of Science and Technology Hisar-125001, India*<sup>b</sup>*Department of Environmental Sciences and Technology, Central University of Punjab, Bathinda 151001, Punjab, India.*<sup>c</sup>*Centre for Life Sciences, Bhartiya University, Coimbatore – 641046, Tamilnadu, India***Corresponding author: Phone +91-9812058109; email [vinodkgarg@yahoo.com](mailto:vinodkgarg@yahoo.com)****Highlights:**

- Fe<sub>3</sub>O<sub>4</sub>@AC nanoparticles were synthesised by co-precipitation methods for basic dye adsorption.
- Maximum adsorption capacity of Fe<sub>3</sub>O<sub>4</sub>@AC was 138 mg/g for MB and 166.6 mg/g for BG dye.
- Adsorption isotherms and kinetic and thermodynamic studies were also performed.
- Reusable potential of adsorbent was also evaluated upto several cycles.

**Abstract:**

This study deals with removal of cationic dyes from simulated wastewater using Fe<sub>3</sub>O<sub>4</sub> nanoparticles loaded activated carbon. (Fe<sub>3</sub>O<sub>4</sub>@AC) nanoparticles were synthesised using co-precipitation methods. The Fe<sub>3</sub>O<sub>4</sub>@AC nanoparticles (nps) were characterised using different techniques and TEM analysis revealed that the synthesized nanoparticles were 6 to 16 nm in diameter. A pHpzc of Fe<sub>3</sub>O<sub>4</sub>@AC nanoparticles was 7.8. BET surface area of Fe<sub>3</sub>O<sub>4</sub>@AC nps was found 129.6 m<sup>2</sup>/g by single point method and 1061.9 m<sup>2</sup>/g by multipoint method. Adsorption experiments were performed to optimize the process conditions such as pH, nanoparticles dose, temperature, and concentration of dye and contact time. The maximum uptake capacity of Fe<sub>3</sub>O<sub>4</sub>@AC was 138 and 166.6 mg/g for methylene blue and brilliant green dyes, respectively. In order to assess dye adsorption behaviour, adsorption isotherm models viz., Langmuir, Freundlich and Temkin were applied. Langmuir isotherm best fitted [R<sup>2</sup>= 0.993 (MB) and R<sup>2</sup>=0.920 (BG)] to the experimental data of both the dyes. Further, Pseudo-second order rate equation fitted better to the experimental data. Reuse potential was

31 also investigated for both dyes and it is inferred from the data that the synthesised  
32 nanoadsorbent has promising reuse potential that can be used for several cycles.

33 **Keywords:** Methylene Blue; Brilliant green; Co-precipitation; Isotherms; Kinetics.

## 34 **Introduction**

35 Cationic dyes are extensively used in several industries such as packaging, textiles,  
36 paper and pulp, printing, leather, pharmaceutical etc. These dyes contain aromatic structure  
37 and azo groups (Yazdanbakhsh et al., 2011). Basic dyes [Brilliant green (BG) and Methylene  
38 blue (MB)] are often used by industries for colouring their products. These industries release  
39 dyes containing effluent into the wastewater streams that may cause several health problems  
40 including irritation in skin, eyes and gastro intestinal tract, vomiting, diarrhoea, coughing,  
41 vomiting etc (Saini et al., 2018; Zolgharnein et al., 2015). These dyes are toxic in nature and  
42 have non-biodegradable organic and inorganic compounds. These dyes also deteriorate the  
43 aquatic environment,. interrupt photosynthesis, growth of the aquatic life etc. Dye containing  
44 wastewater is hazardous and unfit to human life when discharged without any treatment  
45 (Joshi, S et al. 2018). Therefore, the treatment of dye laden industrial wastewater is  
46 unavoidable.

47 Different techniques such as ozonation, adsorption, advance oxidation process etc.  
48 have been adopted for wastewater treatments. Amongst these, adsorption is found to be more  
49 efficient, promising and having easy approach for treatment of dye amalgamated industrial  
50 wastewater (Kataria at al., 2016; Saini et al., 2017). ]. However, choice of suitable adsorbent  
51 is hindered by several factors like cost; reuse potential, eco-friendly nature and field  
52 applications (Saini et al., 2017). Hence, it is important to develop and effective adsorbents. In  
53 recent times nanoadsorbents have emerged as a promising alternate. Nanoadsorbents can be  
54 employed for wastewater treatment due to their peculiar properties such as higher surface  
55 area, lesser production cost, higher efficiency, magnetic character etc. (Joshi et al., 2018;  
56 Kataria at al., 2016; Saini et al., 2017).

57 Recently, magnetite nanoadsorbents like  $\text{Fe}_3\text{O}_4@\text{Ag}/\text{SiO}_2$  [2],  $\text{Fe}_3\text{O}_4@\text{Sawdust}$   
58 carbon and  $\text{EDTA}@\text{Fe}_3\text{O}_4@\text{Sawdust}$  carbon (Kataria and Garg, 2018), sodium dodecyl  
59 sulphate modified  $\text{ZnFe}_2\text{O}_4$  (Mahmoodi, 2015) and  $\text{Fe}_3\text{O}_4$  loaded activated maize cob (Tan et  
60 al., 2012) are reported to have been prepared by surface modification. It is evident from these  
61 studies that surface modifications enhanced the physical as well as chemical properties of

62 nanoadsorbents, so that they become more usable for remediation of pollutants from  
63 industrial wastewater (Joshi et al., 2018; Kataria and Garg, 2018).

64 Activated carbon is extensively used for waste water treatment. But its application is  
65 restricted due to cost. Filtration used in this process also make water turbid and removal of  
66 turbidity is also a matter of concern (Mahmoodi, et al., 2011). But on combining this  
67 traditional adsorbent with nanoadsorbent may make the process easier and cost effective  
68 because nanosize particles are cost effective and have reusable efficiency (Haldorai and  
69 Shim, 2014). The purpose of choosing and synthesizing  $\text{Fe}_3\text{O}_4@\text{AC}$  nps is based on  
70 following hypothesis: a) Activated charcoal contains negative sites ( $\text{O}^{2-}$  and  $\text{OH}^-$ ) and  $\text{Fe}_3\text{O}_4$   
71 nanosphere also having enough  $\text{O}^{2-}$  (negative) sites around  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  which interacts with  
72 the positive sites of cationic dyes. It can enhance the removal percentage and adsorption  
73 capacity for cationic dye. b) Prepared  $\text{Fe}_3\text{O}_4@\text{AC}$  nps adsorbent exhibits magnetic property  
74 so it can be easily separated from waste water and c) Reusability of nanoadsorbents is found  
75 better than other traditional adsorbents. In the present work, iron oxide nanoparticles loaded  
76 activated charcoal was prepared to apply for dye removal from aqueous medium. It was  
77 prepared by co-precipitation method. Cationic dye adsorption was investigated by  
78 experiments performed in batch mode. Adsorption behaviour and rate mechanism were  
79 investigated by isotherm and kinetics modelling. Further, reuse potential of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps  
80 for cationic dyes were checked for several cycles.

## 81 **2. Experimentation**

### 82 **2.1. Reagents & Materials**

83 Ferric nitrate hexahydrate, Tartaric acid, Sodium hydroxide pellets, Methylene blue  
84 dye (MB), Brilliant green (BG) dye and Activated Charcoal (phosphorous free) AR were  
85 purchased from SD fine-chemical Limited, Mumbai. AR grade of chemicals were used in the  
86 present study. More details of cationic dyes are given in Table S1.

### 87 **2.2. Preparation of $\text{Fe}_3\text{O}_4@\text{AC}$ nanoparticles:**

88 Modified co-precipitation process was adopted to prepare  $\text{Fe}_3\text{O}_4@\text{AC}$  nps (Joshi et al., 2018;  
89 Tan et al., 2012). In first stage, solution of  $\text{FeCl}_3$  (0.1M),  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  (0.2M) and tartaric  
90 acid (0.05M) were prepared by mixing together in 100 mL double distilled water (DDW).  
91 The solution was stirred for 30 min. Thereafter, NaOH was added drop wise until brownish  
92 colour precipitates formed. Then, solution was stirred for 2hr and precipitate was filtered and

93 cleaned with DDW. Iron oxide nanoparticles so obtained, were put in oven at 80 °C for one  
94 hr. In second stage, one gram of synthesised nanoparticles was mixed in 70 mL of DDW and  
95 two grams of activated charcoal (AC) was added in this using ultra sonication method to  
96 avoid particle aggregation. The resultant blackish precipitate so obtained was dried in oven at  
97 100°C for 120 min. to obtain the desired material. Scheme S1 shows the graphical  
98 representation of synthesis of Fe<sub>3</sub>O<sub>4</sub>@AC nps.

### 99 **2.3. Characterization and Instrumentation**

100 Particle Size:

101 Dynamic light scattering (DLS) method was used to find out the hydrodynamic  
102 diameter of prepared Fe<sub>3</sub>O<sub>4</sub>@AC nanoparticless by Zetasizer instrument.

103 XRD Analysis:

104 The crystalline structure of Fe<sub>3</sub>O<sub>4</sub>@AC nps was investigated by XRD technique via  
105 (Rigaku miniflex II Diffractometer), by Cu-K<sub>α</sub> X-ray radiations at room temperature in the 2θ  
106 range of 20°-80°at scanning rate of 2°/min.

107 TEM Analysis:

108 Transmission electron microscopy was performed to investigate the particle size of  
109 Fe<sub>3</sub>O<sub>4</sub>@AC nps by means of FEI Tecnai G<sup>2</sup> 20 TWIN electron microscope at 200 KV.

110 FTIR Analysis:

111 To analyse the functional groups in the synthesised nanoadsorbents, FTIR study was  
112 performed using Shimadizu IR AFFINITY-1 spectrophotometer using KBr powder pellet.

113 SEM Analysis:

114 The elemental analysis and morphology of surface of Fe<sub>3</sub>O<sub>4</sub>@AC nps were estimated  
115 via Scanning electron microscopic (SEM) technique and Energy-dispersive X-ray (EDX)  
116 analysis which was performed by Merlin compact 6073 scanning electron microscope (Carl  
117 Zeiss, Germany).

118 pH at point zero charge:

119 The pH at point zero charge was calculated by early reported NaNO<sub>3</sub>addition method.  
120 Instrumentation details for characterisation are already reported in our previous studies.  
121 (Joshi et al., 2018; Saini et al., 2017).

### 122 **2.4. Batch adsorption experiments**

123 Batch mode study was undertaken under dark conditions, to optimize the different  
124 parameters (dye concentration, pH, adsorbent dose, time etc.). Dye adsorption experiments

125 were performed in 50mL of 50 mg/L of MB and BG dye solutions in an Erlenmeyer flask at  
126 room temperature ( $27\pm 1^\circ\text{C}$ ) using orbital shaker. Shaking speed used was 200 rpm.  
127 Adsorbent dosages were changed from 0.010 g to 0.040 g/50mL, dye concentration used was  
128 between 30 mg/L to 100 mg/L, mixing time was 20-120 min and solution pH was set from 2  
129 to 10 by adding 0.01N solution of HCl or NaOH. The pH of solutions was measured by pH  
130 meter (Eutech Instruments, Singapore). UV-VIS spectrophotometer used to quantify the dye  
131 concentration. Centrifuge of Dye solutions containing  $\text{Fe}_3\text{O}_4@\text{AC}$  nps was performed at  
132 10000 rpm for ten minutes. Absorbance was measured at  $\lambda_{\text{max}}$  664 nm for MB dye and  $\lambda_{\text{max}}$   
133 626 nm for BG dye. Removal (%) of dyes and adsorption capacity for dyes were estimated  
134 using the following equations:

$$\text{Dye removal (\%)} = \frac{(C_o - C_e)}{C_o} \times 100 \quad (1)$$

$$\text{Adsorption capacity } (q_e) = \frac{(C_o - C_e) V}{m} \quad (2)$$

135 Where  $m$  in grams represents the mass of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps,  $C_o$  in mg/L represent initial dye  
136 concentration,  $C_e$  in mg/L is equilibrium dye concentration,  $q_e$  in mg/g represent amount of  
137 dye adsorbed per unit of the adsorbent at equilibrium and volume of dye solution is  $V$  (L).

### 138 3. Results for discussion

#### 139 3.1. $\text{Fe}_3\text{O}_4@\text{AC}$ nps Characterization

140 Fig. 1a depicts the characteristic peaks of synthesized  $\text{Fe}_3\text{O}_4@\text{AC}$  nanoparticles in  
141 XRD patterns which were recorded using X-ray diffractometer at  $2\theta = 30.3^\circ, 35.6^\circ, 45.5^\circ,$   
142  $60^\circ$  and  $65^\circ$  and the observed peaks were matched to diffraction planes (511), (440), (422),  
143 (400), (311), and (220), respectively. These observations matched with earlier studies (Loh  
144 et al., 2008; Seyedsadjadi et al., 2014; Ding et al., 2012).

145 Fourier Transform Infra Red (FTIR) spectroscopy used in the present study was to  
146 find out the different functional groups and sites which are available for bindings of the  
147 synthesized nanoparticles. In Fig. 1b, the activated charcoal (AC) exhibits absorption bands  
148 at  $3420\text{ cm}^{-1}, 3120\text{ cm}^{-1}, 2320\text{ cm}^{-1}, 1725\text{ cm}^{-1}$  and  $1178\text{ cm}^{-1}$ . The broad peak at  $3420\text{ cm}^{-1}$  is  
149 due to OH stretching of H-bond which shows the presence of hydroxyl group. The  
150  $\text{Fe}_3\text{O}_4@\text{AC}$  exhibits absorption peaks at  $2320\text{ cm}^{-1}, 3420\text{ cm}^{-1}, 1725\text{ cm}^{-1},$  and  $1588\text{ cm}^{-1}$ .

151 Here, two more peaks are observed at  $698\text{ cm}^{-1}$  and  $487\text{ cm}^{-1}$  which show the presence of iron  
152 oxide in the prepared sample (Reza and Ahmaruzzaman, 2015).

153 Scanning electron micrographs (Fig. 1c) were used to study surface morphologies and  
154 texture of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps at different magnification. The SEM image reveals that the  
155 particles are not completely spherical. EDX image gives the elemental composition i.e. it  
156 contains iron, oxygen and traces of copper and chlorine as impurities as shown in Fig. 1d.  
157 DLS spectra were analysed using hydrodynamic size distribution of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps. The size  
158 distribution of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps was found in between 100-1000 d.nm as observed in Fig. 1e.

159 Nitrogen adsorption–desorption isotherm plots between relative pressure ( $P/P^0$ ) and  
160 adsorbed volume ( $\text{cc/g}$  at STP) of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps are shown in Fig. 1f. BET surface area of  
161  $\text{Fe}_3\text{O}_4@\text{AC}$  nps at single point method and multipoint method was found to be  $129.6\text{ m}^2/\text{g}$   
162 and  $1061.9\text{ m}^2/\text{g}$ , respectively. The values of BJH pore volume and pore diameter of  
163 adsorbent were  $0.0206\text{ cc/g}$  and  $3.6\text{ nm}$ , respectively. Total pore volume and Average pore  
164 diameter were found to be  $0.54\text{ cc/g}$ , and  $16.6\text{ nm}$  respectively.

165 TEM images are shown in Fig. 2a-d which reveal that nanoparticles are in the range  
166 of 6 -16 nm. Perusal of the Fig. 2 shows that the synthesized  $\text{Fe}_3\text{O}_4@\text{AC}$  nps are very fine  
167 and their cluster shows that activated charcoal is fully incorporated in  $\text{Fe}_3\text{O}_4$  particles. SAED  
168 (selected area electron diffraction) pattern also indicates the low crystallinity of the  
169 synthesised  $\text{Fe}_3\text{O}_4@\text{AC}$  nps due to amalgamation of activated carbon as evidenced by broad  
170 diffraction rings in Fig. 2c. The pH at point of zero surface charge ( $\text{pHpzc}$ ) of synthesized  
171 nanoparticles was 7.8, calculated from plot between  $\Delta\text{pH}$  ( $\text{pHi} - \text{pHf}$ ) versus  $\text{pHi}$  as given in  
172 Fig. 3a. At  $\text{pH} = 7.8$ , surface of material contains identical number of positive and negative  
173 charge functional groups or ions.

## 174 **3.2. Batch Adsorption studies**

### 175 **3.2.1. The pH effect study**

176 For both cationic dyes such as MB and BG, effect of pH was investigated within the  
177 pH range from 2 to 10. The present study was performed with  $0.025\text{ g}/50\text{ mL}$  of dose in  $50$   
178  $\text{mg/L}$  of dye concentration at room temperature for 2 h. Perusal of the data presented in Fig.  
179 3b shows that with increase in pH from 2 to 10, dye removal was also increased from  $84.3$   
180  $\%$  to  $100\%$  and  $55.6\%$  to  $91.8\%$  for MB and BG dyes, respectively. The pH effect on dye  
181 exclusion can be understood by the competition between positive ions of cationic dyes and

182  $H^+$  ions at low pH. The pHPzc of  $Fe_3O_4@AC$  nanoparticle was 7.8 (Fig. 3b). The pH below  
183 pHPzc, surface of adsorbent was positively charged which repel cationic dye molecules. With  
184 increase in pH above pHPzc, negatively charged surface of adsorbent attract positively  
185 charged dye molecules and number of  $H^+$  ions decreases rapidly causing less competition  
186 between  $H^+$  ions and cationic dye molecules adsorbed at active sites (Kataria and Garg, 2019).  
187 The result showed that the pH of the solution has significant effects on the adsorption,  
188 suggesting thereby that the ionization of the adsorbate and the surface charge are varied as  
189 the charge of pH of solution. The observed trend may also be explained as follows: At lower  
190 pH, the electrostatic repulsion between molecules of cationic dyes and  $H^+$  ions of adsorbent  
191 surface is higher which results in less dye removal. At higher pH values, the surface adheres  
192 negative charge and thus the competition for  $H^+$  ions becomes less which causes more dye  
193 removal (Wu et al., 2016; Ali et al., 2017; Saini et al., 2018).

### 194 3.2.2. Initial dye concentration and its effect

195 Fig. 3c depicts the effect of initial dye concentration (30 mg/L to 100 mg/L), on the removal  
196 of cationic dyes within the range of dye concentration, from the figure, showed the adsorption  
197 of dye molecules decreased with increase in dye concentration. At 30 mg/L, the removal was  
198 100% for both MB dye and BG dye while at 100 mg/L the removal was only 69.9% for MB  
199 and 83.8% for BG. This might be due to accessibility of additional active sites on adsorbent  
200 surface for dye adsorption at low concentration of dyes while due to less availability of  
201 surface-active binding sites with increase in dye concentration because of saturation of  
202 binding site with dye molecule (Rehman et al., 2013; Wu et al., 2016; Saini et al., 2018) the  
203 dye removal tendency decreases.

### 204 3.2.3. Adsorbent dose effect

205 Effect of adsorbent dose for adsorption of cationic dyes was performed using 50 mL  
206 of dye solution with 50 mg/L of dye concentration at room temperature for two hours. The  
207 adsorption was changed in the range from 0.01 to 0.04 g (Fig. 3d). For BG dye, with increase  
208 in adsorbent dose, dye removal was continuously increased from 73.8 to 100 %. Similar  
209 behaviour was viewed in MB dye i.e., removal was increased from 94.3 to 100 %. Both the  
210 dyes achieved maximum adsorption at 0.04 g dose and which was 100 %. It may be due to  
211 accessibility of additional active binding sites and surface area for cationic dyes with  
212 increased in adsorbent dose (Wu et al., 2016; Jia et al., 2016; Kataria and Garg, 2017; Joshi et

213 al., 2018). However, when the dosage becomes 0.04g, the adsorbents afford adequate number  
 214 of active sites that react completely with the molecules of cationic dyes.

#### 215 **3.2.4. Contact time and its effect**

216 Fig. 3e, f shows the effect of contact time which varied from 0.0 to 120 min for both  
 217 the MB and BG dyes. The batch mode studies were conducted in 250 mL Erlenmeyer flasks  
 218 with 50 mL of dye solutions of different dye concentrations (30-100mg/L) using 0.025g/50  
 219 mL of adsorbent dose at  $27\pm 1^\circ\text{C}$ . There was fast enhancement in adsorption process with  
 220 increase in contact time up to 20 min. It may be due to the availability of large number of free  
 221 surface active sites for dye adsorption. Thereafter, was slight increase in dye removal and  
 222 then attains equilibrium at 120 min. This suggests that no more active sites are produced for  
 223 dye adsorption after the maximum surface area occupied by the dye molecule is attained  
 224 (Duman et al., 2016; Kataria and Garg, 2019).

#### 225 **3.2.5. Effect of thermal treatment**

226 The result of effect of temperature was obtained for MB and BG dyes, in range from  
 227 10 to  $50^\circ\text{C}$ , with 50 mg/L dye concentration for 120 min. It was found that both the dyes  
 228 showed almost identical behaviour with respect to variation of temperature as shown in Fig.  
 229 3g. The dye removal percentage was enhanced from 81% to 93.5 % for MB dye and 76.94%  
 230 to 92.1% for BG dye, with increase in temperature. The phenomenon is attributed to the fact  
 231 that the due to raise in temperature, the contact of dye molecules with the adsorbents surface  
 232 active sites were also increases. Hence, it results in increased mobility and diffusion of  
 233 cationic dye molecules in aqueous solution. The adsorption experiments were performed at  
 234 room temperature (Bhagat et al., 2014; Kataria and Garg, 2017).

### 235 **3.3. Thermodynamic behaviour study**

236 Parameters of thermodynamics such as changes in, ( $\Delta S^\circ$ ) entropy, ( $\Delta G^\circ$ ) Gibb's free  
 237 energy and ( $\Delta H^\circ$ ) enthalpy for the adsorption of cationic dyes on  $\text{Fe}_3\text{O}_4@\text{AC}$  nps have been  
 238 investigated by using temperature variation experiments. Following equations are made  
 239 (Saini et al., 2018; Smith and Ness, 1987) use of:

$$240 \Delta G^0 = -RT \ln K_d \quad (3)$$

$$241 K_d = \frac{C_a}{C_e} \quad (4)$$

$$\ln K_d = -\frac{\Delta H^0}{RT} + \frac{\Delta S^0}{R} \quad (5)$$

240 Where  $K_d$  is the equilibrium constant,  $R$  is gas constant ( $8.314 \text{ J mol}^{-1}\text{K}^{-1}$ ),  $T$  (K) is  
 241 temperature and  $C_a$ (mg/L) is the quantity of MB and BG dyes on the nanoadsorbent surface  
 242 at equilibrium. The  $\Delta H^\circ$  and  $\Delta S^\circ$  were determined from the slope and intercept values of  
 243 linear plots between  $\ln K_d$  and  $1/T$  (Fig. 3h). Table 1 illustrate that the adsorption process for  
 244 both the dyes is endothermic due to positive values of  $\Delta H^\circ$ , which in turn indicates that both  
 245 the dyes are absorbed by physical process (Kataria and Garg, 2017). The positive value of  
 246  $\Delta S^\circ$  for MB dye ( $104.49 \text{ J mol}^{-1}\text{K}^{-1}$ ) and for BG dye ( $92.18 \text{ J mol}^{-1}\text{K}^{-1}$ ) confirm that the  
 247 increase in the degree of mobility at the solid-solution interface which enhance the adsorption  
 248 dye molecules. The adsorption feasibility and spontaneity for MB and BG dyes were  
 249 ascertained by negative value of  $\Delta G^\circ$ , which is illustrated in Table 1.

### 250 3.4. Adsorption Kinetics

251 Pseudo-first order (Langergren, 1898) and pseudo-second order (Mckay and Ho,  
 252 1999) models were made use of to investigate the rate mechanism of adsorption of cationic  
 253 dyes onto prepared  $\text{Fe}_3\text{O}_4@AC$  nps. The linear forms are represented by the following  
 254 expressions.

$$\log(q_e - q_t) = \log q_e - \left(\frac{k_1}{2.303}\right)t \quad (6)$$

$$t/q_t = 1/k_2 q_e^2 + t/q_e \quad (7)$$

$$q_t = k_{id}t^{1/2} + C \quad (8)$$

255 Where,  $(q_e)$  at equilibrium time is the adsorption capacity,  $(q_t)$  at time  $t$  is the adsorption  
 256 capacity,  $k_1$  ( $\text{min}^{-1}$ ) is the rate constant for pseudo-first order,  $k_2$  ( $\text{min}^{-1}$ ) is the pseudo-second  
 257 order rate constant. The parameters of kinetic models are illustrated in Table 2. It was  
 258 calculated from the experimental data by applying linear regression analysis to the linear  
 259 form of all the models. Fig. 4(a-d) depicts the linear plots of pseudo-first order and pseudo-  
 260 second order models. The values of  $k_1$ , and  $q_e$  were found by the plot of  $\log(q_e - q_t)$  vs  $t$  for  
 261 pseudo-first order model and the plot of  $t/q_t$  versus  $t$  for the pseudo-second order model. The  
 262  $q_e$  (calculated) value determined from plot is less than  $q_e$  (experimental) value as illustrated in  
 263 table for both the cationic dyes suggesting that the pseudo-first order was not best fitted while  
 264 values of Pseudo-second order regression coefficient, ( $R^2 = 0.999$ ) of both the basic dyes are

265 bigger than that of pseudo-first order which shows the applicability of the later, Also the  $q_e$   
 266 (cal) values are nearer to or almost equal to  $q_e$  (exp) values obtained from adsorption  
 267 experiments of both the dyes for pseudo-second order model. Hence, pseudo-second order  
 268 model is best suited for both the dyes.

269 For intraparticle diffusion model,  $k_{id}$  is intraparticle diffusion constant and C is intercept  
 270 which gives the approximate boundary layer thickness. The values of  $k_{id}$  and C were getting  
 271 from intercept and slope, respectively, of the curves of the plot between  $q_t$  versus  $t^{1/2}$ .  
 272 Intraparticle model, assumed that both the dye molecules (BG and MB) were moving towards  
 273 the pores of the adsorbents from bulk solutions through boundary layers (Kataria and Garg,  
 274 2018a). Table 3 shows the higher values of C for MB and BG dyes which suggest the  
 275 involvement of boundary layer thickness for cationic dyes adsorption. Two different linear  
 276 curves are shown in Fig 4(e,f) suggesting the involvement of two stage process for both the  
 277 cationic dyes adsorption. Firstly, bulk of dye molecules migrated towards boundary layer of  
 278 adsorbent. Secondly, linear layer shows the intraparticle diffusion and then achieving  
 279 equilibrium hence, the rate mechanism of cationic dye adsorption was controlled by  
 280 intraparticle diffusion and boundary layer diffusion both.

### 281 3.5. Equilibrium isotherm models

282 Adsorption behaviour and interaction between adsorbent and dye molecules were  
 283 interpreted using isotherm models (Langmuir, 1916). Langmuir, Freundlich and Temkin &  
 284 Pyzhev adsorption isotherm models were applied to the adsorption data to explain the  
 285 adsorption equilibrium of cationic dyes onto  $Fe_3O_4@AC$  nps. Linear form of Langmuir  
 286 isotherms model (Langmuir, 1918) is given as.

$$\frac{C_e}{q_e} = \frac{1}{q_{max}b} + \frac{C_e}{q_{max}} \quad (9)$$

287 Where  $b$  (L/mg) is the Langmuir constant,  $q_{max}$  (mg/g) is the maximum monolayer adsorption  
 288 capacity.

289 Freundlich isotherms model (Freundlich, 1906) may be represented by the equation:

$$\log q_e = \log K_f + \frac{1}{n} \log C_e \quad (10)$$

290 Where  $K_f$  is a Freundlich constant (related to adsorption capacity) and  $1/n$  is the heterogeneity  
 291 factor (related to intensity of adsorption) and its value should be lie within 0 and 1 to make  
 292 adsorption process favourable. The value of  $1/n$  near zero indicates heterogeneous surface,

293 1/n less than 1, indicates chemisorption and 1/n greater than 1, indicates cooperative  
294 adsorption (Foo and Hameed, 2010, Kataria and Garg, 2019)

295 Temkin isotherms model (Temkin and Pyzhe, 1940) is given by the expression:

$$q_e = B \ln K_T + B \ln C_e \quad (11)$$

296 Where  $R$  ( $8.314 \text{ J mol}^{-1}\text{K}^{-1}$ ) is the gas constant,  $B = RT/b$ ,  $b$  (J/mol) is the Temkin  
297 constant which indicates the heat of adsorption,  $T$  (K) is absolute temperature and  $K_T$  (L/g) is  
298 equilibrium binding constant. Correlation coefficients and Model parameters for MB dye and  
299 BG dye are encapsulated in Table 3. The linear plots of isotherm models are shown in Fig.  
300 5(a-c). The highest correlation coefficient for MB dye ( $R^2 = 0.993$ ) and BG dye ( $R^2 = 0.920$ )  
301 were found using Langmuir model. comparison of studied isotherms models suggested that  
302 the Langmuir model better described the adsorption of both the dyes than Temkin and  
303 Freundlich model. This shows the monolayer adsorption of cationic dyes on  $\text{Fe}_3\text{O}_4@\text{AC}$  nps.  
304 The maximum adsorption capacity of MB and BG dyes were  $138.8 \text{ mg/g}$  and  $166.6 \text{ mg/g}$ ,  
305 respectively. The adsorption capacities of MB and BG dyes with other reported adsorbents  
306 are listed in Table 4. This information suggest that the  $\text{Fe}_3\text{O}_4@\text{AC}$  nps have potential to  
307 remove cationic dyes from simulated waste water.

### 308 **3.6. Adsorption mechanism for dye removal onto $\text{Fe}_3\text{O}_4@\text{AC}$ nps**

309 Adsorption by nanoparticles for cationic dye elimination is influence by several factors such  
310 as availability of functional groups, surface charge, pH etc .These factors determines the  
311 mechanism of the investigation related to dye adsorption behaviour (Kataria and Garg, 2019).  
312 In the present work, iron oxide nanoparticles loaded activated charcoal was prepared to apply  
313 for dye removal from aqueous medium. Here the possible mechanism was explained on the  
314 basis of surface charge and functional groups present on both the adsorbate and adsorbent  
315 system. Activated charcoal contains negative sites ( $\text{O}^{2-}$  and  $\text{OH}^-$ ) which interact with positive  
316 ions. Similarly,  $\text{Fe}_3\text{O}_4$  nanosphere also having lots of available  $\text{O}^{2-}$  (negative) sites around  
317  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  atom which interacts with the positive sites of both the cationic BG and MB  
318 dye. Furthermore when we utilize iron oxide nanoparticles loaded activated charcoal  
319  $\text{Fe}_3\text{O}_4@\text{AC}$  then we got more negative active available sites for our experimental system of  
320 basic dyes removal which enhances the interaction among adsorbent and adsorbate surface  
321 hence, there is increase in removal percentage and adsorption capacity for cationic dye  
322 removal by synthesised nanoadsorbent. (Saini et al., 2018). Fig.6 shows the possible  
323 adsorption mechanism for dye removal onto  $\text{Fe}_3\text{O}_4@\text{AC}$  nps.

### 324 **3.7. Reuse Potential of Adsorbent**

325 In the present work, reusability of the  $\text{Fe}_3\text{O}_4@\text{AC}$  nps was investigated by performing four  
326 cycles of dye removal experiments as shown in Fig.5d. The adsorbent was separated from the  
327 aqueous medium by centrifugation, after the completion of adsorption experiments.  
328 Thereafter it was washed using ethanol and distilled water for a number of times then  
329 dehydrated in oven for few hours at 80 °C. The regenerated adsorbent was further used for  
330 adsorption of cationic dyes. In the first cycle the removal percentages for BG dye was 74.5%  
331 and for MB dye 79.2% respectively. After third cycle, the removal (%) was slightly reduced  
332 in for both the dyes and thereafter, became constant in fourth cycle as shown in Fig. 5d. It  
333 suggests that  $\text{Fe}_3\text{O}_4@\text{AC}$  nps have good reusable efficiency and can be used for several  
334 cycles.

### 335 **4. Conclusions.**

336 In this work  $\text{Fe}_3\text{O}_4@\text{AC}$  nps have been synthesised by co-precipitation method and  
337 exhibited good adsorption behaviour towards cationic dyes under the optimum process  
338 conditions. Further its efficiency was compared with other synthesised nanoadsorbents for  
339 cationic dyes removal and it was found to be more efficient than others. The maximum  
340 adsorption capacities for MB and BG dyes were found to be 138 mg/g and 166.6 mg/g,  
341 respectively. Langmuir model is best fitted in dye adsorption data which indicates the  
342 monolayer adsorption of dye molecules on the surface of  $\text{Fe}_3\text{O}_4@\text{AC}$  nps. Pseudo-second  
343 order model was suited in both the cationic dyes adsorption data. This observation reveals  
344 that the  $\text{Fe}_3\text{O}_4@\text{AC}$  nanoadsorbent has a significant potential for the adsorption of MB and  
345 BG dyes from aqueous medium and can be reused for several cycles successfully.

### 346 **Acknowledgement**

347 One among the authors (Ms. Seema Joshi) is thankful to University Grants Commission, New  
348 Delhi India for providing the financial assistance in the form of BSR-UGC Fellowship.
